Analytic Framework Description : Client Reminder and Recall Systems to Increase Vaccination Rates

The analytic framework shows how client reminder and recall interventions would be expected to increase vaccination rates. Client reminder or recall interventions can be one component of a larger vaccination database or registry system. Interventions deliver information about vaccination to clients who are due (reminders) or overdue (recall) for vaccination. This is expected to increase client knowledge about their vaccination status and increase client motivation to obtain that vaccination. It is postulated this would increase client vaccination rates which would then reduce vaccine-preventable disease and associated morbidity, and mortality.
